

AE 244
Low Speed Aerodynamics

Prof: Dhwanil Shukla

Assignment - 3

Ghoshank Nanhe
22B0073

Contents

1. Wing Design

- 1.1. Full description of wing designed (airfoil, taper, angle of attack, twist, sweep, dihedral, other devices and attachments if any)
- 1.2. CL vs α curves of the wing for $\alpha = -2$ to 10 in increments of 2 computed using the lifting line theory and OpenVSP (in the same plot).
- 1.3. CD vs α curves of the wing for $\alpha = -2$ to 10 in increments of 2 computed using the classical method (induced drag + empirical parasitic drag) and OpenVSP (in the same plot)
- 1.4. CL vs α of the wing and Cl vs α of the constituent airfoil for $\alpha = -2$ to 10 in increments of 2 as computed using OpenVSP on the same plot
- 1.5. Main observations and interpretations from sections 1.2, 1.3, and 1.4.

2. Fuselage Design

- 2.1. CAD of the fuselage
- 2.2. Lift and drag estimates from OpenVSP at $\alpha = -2$ to 10 in increments of 2
- 2.3. Parasitic drag estimates based on empirical method
- 2.4. Comparison of drag results from 2.2 and 2.3, and comments

3. Stabilizer Design

- 3.1. Horizontal and Vertical stabilizer designs (dimensions, airfoil, sketch/CAD)
- 3.2. CL vs α curves for both stabilizers for $\alpha = -3$ to 3 in 1 increments using OpenVSP
- 3.3. CD vs α curves for both stabilizers for $\alpha = -3$ to 3 in 1 increments using OpenVSP
- 3.4. Comments on findings from 3.2, 3.3.

4. Overall glider design

- 4.1. Overall glider design (placement of wing, stabilizers, fuselage, pilot) and CAD .
- 4.2. Performance of the entire glider using Open VSP (CL & CD vs α)
- 4.3. Glider component weight estimates (using CAD) and total weight.

5. Design Validation

- 5.1. Optimal speed, glide angle, range, descent rate for the designed glider
- 5.2. Comment on glider performance w.r.t original requirement and possible scope for improvements.

6. Acknowledgement

- 6.1. Mandatory to acknowledge people you discussed with or took help for any part of the assignment.

7. References

- 7.1. List all references (books, paper, websites, etc.) used while doing the assignment.

1. Wing Design:

1.1. Full description of wing designed

NACA	4311
Taper Ratio	0.76
Angle of Attack	0
Twist	0 Degree
Sweep	5 Degree
Dihedral	4 Degree

Shaded Wing

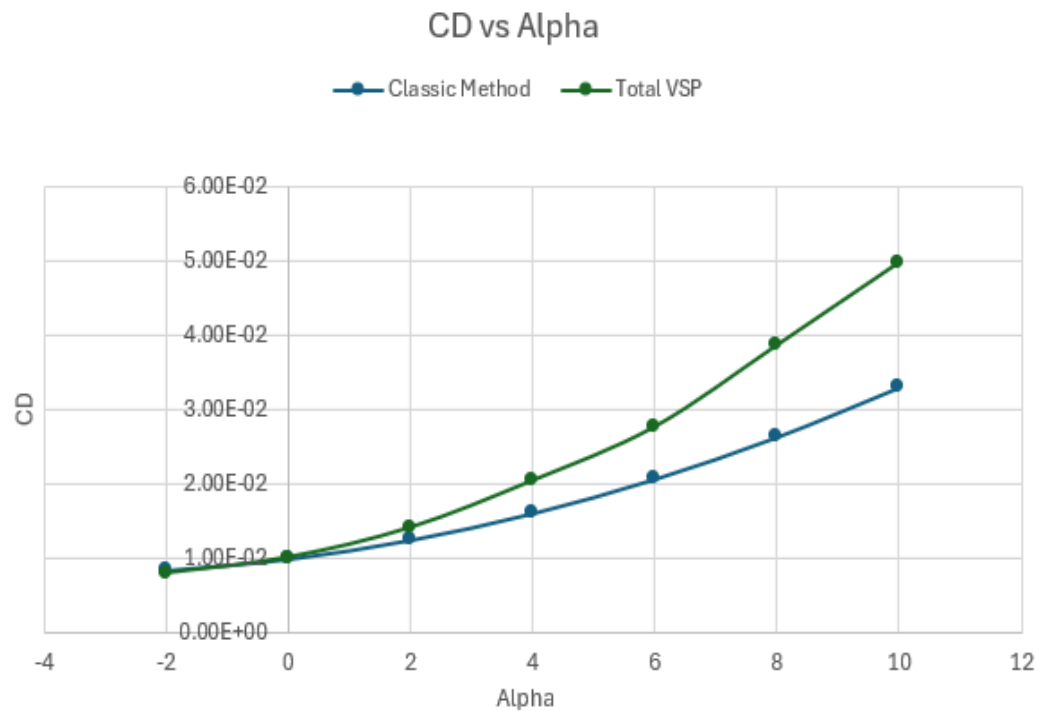

Wing Wire Frame

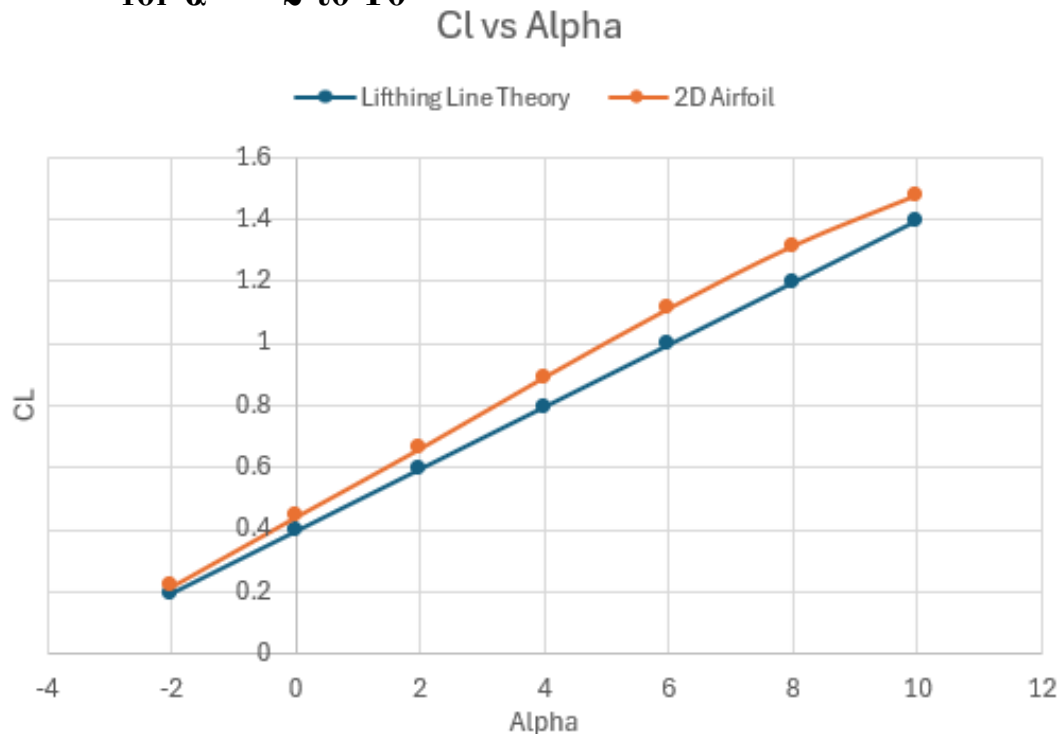

1.2 CL vs α curves of the wing for $\alpha = -2$ to 10

1.3 CD vs α curves of the wing for $\alpha = -2$ to 10

1.4 CL vs α of the wing and Cl vs α of the constituent airfoil for $\alpha = -2$ to 10

1.5 Main observations and interpretations from sections 1.2, 1.3, and 1.4

- In 1.2 curves are almost overlapping on each other, still it is little deflected because in glider wings have dihedral which are accounted by the vsp model but lifting line theory do not account for it.
- They have less error because the dihedral give to the wings is 4 degree and it is very little so it the we get almost similar result.
- In 1.3 Cd curve for lower angle of attack matches in both the methods and when angle increase it begins to deflect,
- In 1.4 Cl from lifting line theory and 2D airfoil have same Angle of attack at which they have zero Cl value, both are similar but wing curve have less slope as compared to 2D wing this is because in 2D airfoil we dont consider down wash and vortices, in wing is is taken into account we leads to reduction in Cl for same angle of attack.

2. Fuselage Design

2.1 CAD of the fuselage

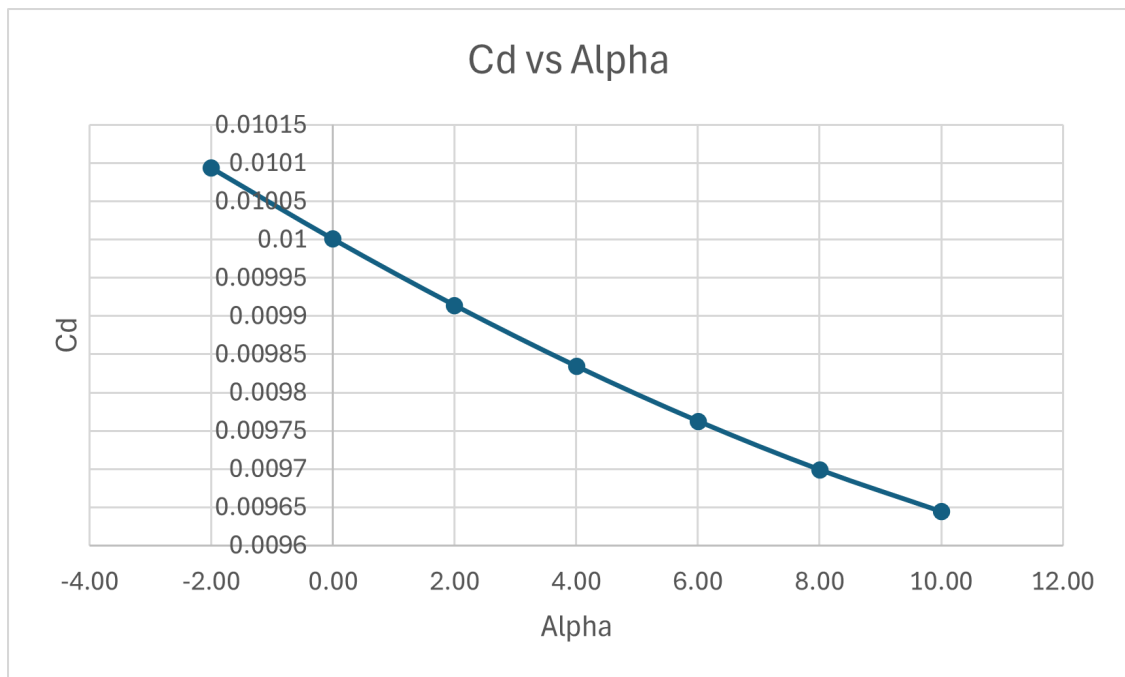

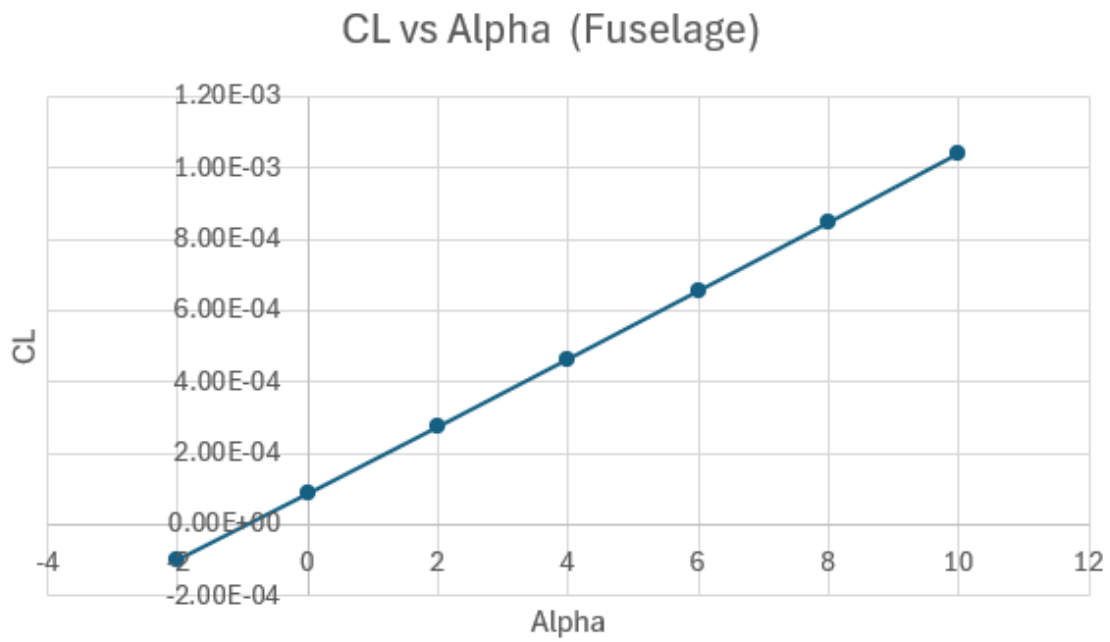

Fuselage Wire Frame

Shaded Fuselage

2.2 Lift and drag estimates from OpenVSP at $\alpha = -2$ to 10

2.3 Parasitic drag estimates based on empirical method

$$Re_L = \frac{\rho_\infty U_\infty L}{\mu_\infty} \quad (L \text{ is fuselage length})$$

$$\bar{C}_f = \frac{0.455}{(\log_{10} Re_L)^{2.58}} - \frac{1700}{Re_L}$$

$$C_{D_0} = \sum_{i=1}^N \frac{K_i \bar{C}_{f_i} S_{\text{wet}_i}}{S_{\text{ref}}}$$

$$R_e = \frac{1.225 \times 30 \times 9.14}{1.5 \times 10^{-5}} = 2.24 \times 10^7$$

$$\bar{C}_f = 2.57 \times 10^{-3}$$

$$C_{D_0} = 0.01014$$

2.4 Comparison of drag results from 2.2 and 2.3, and comments

- In 2.2 C_l vs α have positive slope because fuselage look little similar to a airfoil having positive camber.
- The curve is linear because open vsp do not consider the flow separation thats why it do not show stall.
- C_d vs α curve is decreasing, it is estimated by open vsp which we calculated by adding induced drag and parasitic drag.
- Drag estimated by empirical method is constant as compared to the total drag which is combination of variable induced drag and parasitic drag.

3. Stabilizer Design

3.1 Horizontal and Vertical stabilizer designs

- **Vertical Stabilizer**

- $NACA = 0009$
- $Semi-span = 2.6m$
- $Avg\ Chord = 0.86$
- $Taper\ Ratio = 0.76$
- $Sweep = 22.2\ Degree$

- **Horizontal Stabilizer**

- $NACA = 0009$
- $Span = 6m$
- $Avg\ Chord = 0.86m$
- $Taper\ Ratio = 0.76$
- $Sweep = 11\ Degree$

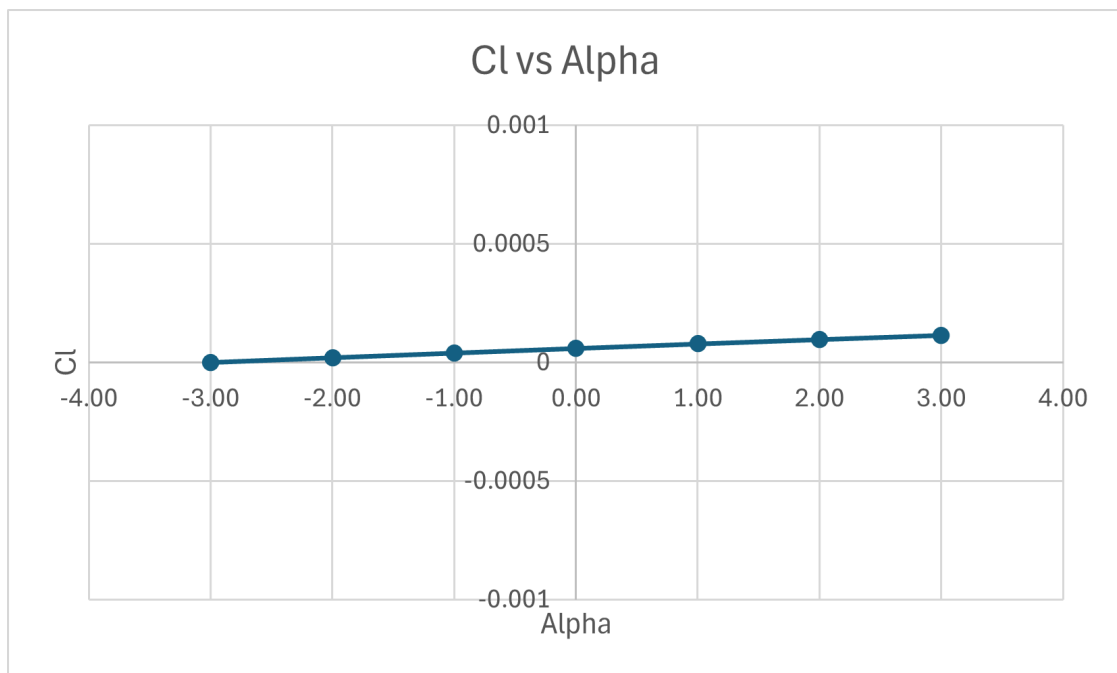

- Both the airfoils are selected to be symmetric to ensure balanced aerodynamic performance. It helps maintain stability and control during flight.
- The horizontal stabilizer is located on top of the vertical stabilizer to improve the vertical stabilizer's aerodynamic efficiency.
- In this the center of Pressure is above the horizontal plane which leads to a steady equilibrium about central axis of the fuselage.
- Sweep is used to reduce the Drag,

3.2 CL vs α curves for both stabilizers for $\alpha = -3$ to 3

- Horizontal Stabilizer

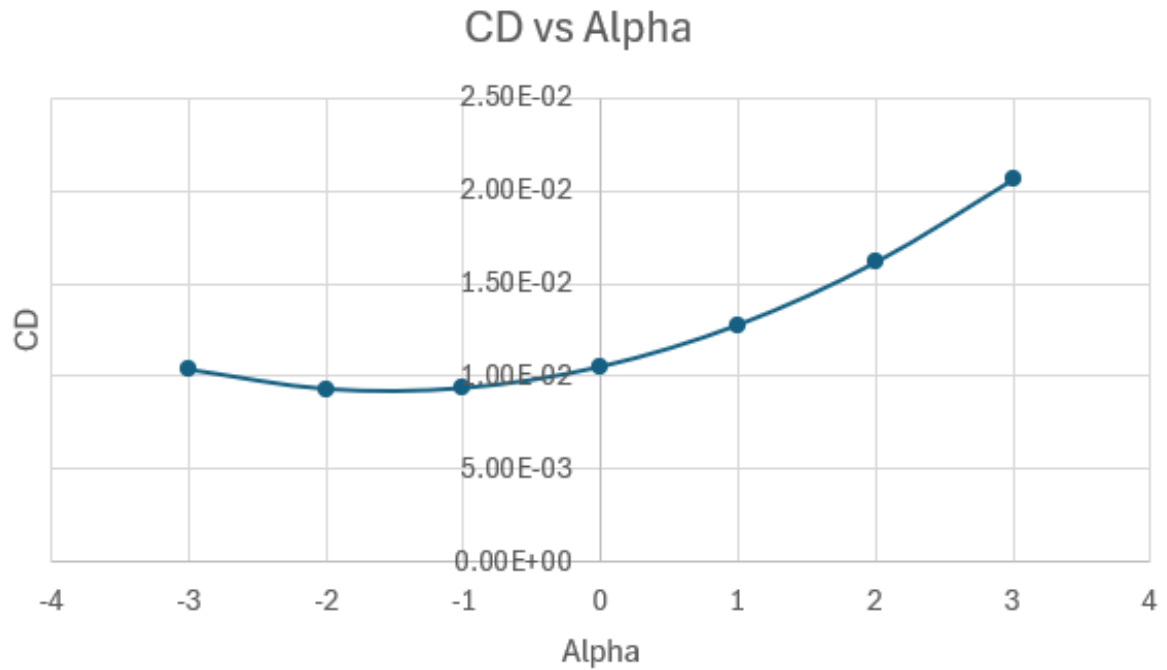

- Vertical Stabilizer

3.3 CD vs α curves for both stabilizers for $\alpha = -3$ to 3

- **Horizontal Stabilizer**

- **Vertical Stabilizer**

3.4 Comments on findings from 3.2, 3.3.

- The stabilizer are used to maintain a stable flight in yaw ,roll and pitch motion.
- The horizontal stabilizer and vertical stabiliser are symmetric airfoil shapes so it can maintain its stability and give zero lift at zero angle of attack with respective their chord.
- C_l values for horizontal stabilizer are higher as compared to vertical stabilizer, this is because vertical stabilizer is vertical and it does not make any sense to calculate for it and it is symmetric so values are near to zero.
- For horizontal stabilizer , it is mounted at a positive angle of attack so it is giving positive C_l at zero angle of attack, note that it is symmetric.

4. Overall glider design

4.1 Overall glider design and CAD

Glider Wire Frame

Shaded Glider

Fuselage

Wing

6 ft Human seating in cockpit

Vertical Stabilizer

Horizontal Stabilizer

- Wings of the glider have high wing configuration to maintain steady equilibrium about the central axis of fuselage.
- These wings also have dihedral in its wing, which makes it more stable in Roll motion.
- Aspect Ratio of this glider is 30:1, which will give more lift as wing span increases, fuselage is half the length of wings.
- Fuselage is made in such a way a person 6 feet high can sit in it with his legs spread forward.
- Wings are tapered. It tries to mimic the elliptical wing, which helps in reducing induced drag and which leads to an increase in Lift.
- Horizontal and vertical stabilizer are symmetric to avoid any unnecessary force on glider while pitching and doing yaw.
- At higher angle of attack the flow behind the wing will become turbulent due to formation of vortex and flow separation, in this we have horizontal stabilizer mounted above the vertical stabilizer which will prevent the horizontal stabilizer from stall and turbulent vortex containing flow.

4.2 Performance of the entire glider using Open VSP

- **Cl vs Alpha**

- **Cd vs Alpha**

4.3 Glider component weight estimates (using CAD) and total weight

- **Surface Areas and Volumes**

Components	Surface Area (m^2)	Volume(m^3)
Main Wing	48.11	1.503
Stabilizer	13.09	0.317
Fuselage	21.55	0.612

- **Weight Estimations**

Compoents	Material	Weight (kg)
Wings, Fuselage, Stabilizers	Carbon Fibre	342.1
Fuselage Spars	Aluminium	159.37
Wings and Stabilizer Spars	Aluminium	315.46
Human	-	80
Total	-	967.08

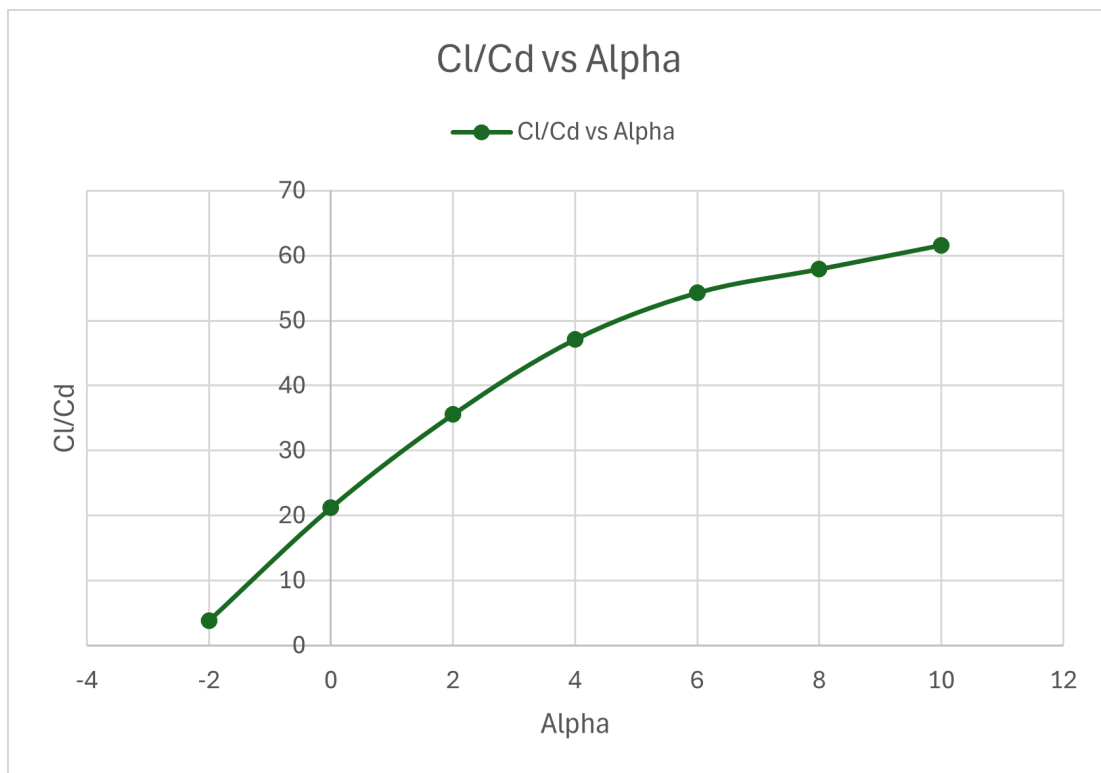

- Components of glider are made up Carbon Fibre and Aluminium.
Carbon Fibre is used to make the skin of the glider which is exposed to external environment and Aluminium is used to make the spars to make a skeleton like structure to support the skin and provide rigidity and strength.
- We considered that the 1/8th volume of fuselage is consumed by the aluminium spars and the 1/16th of Stabilizer area is consumed by spars.
- Weight is calculated on the basis of their density and based on their thickness.
- Carbon Fiber and Aluminium is selected due to their higher strength to weight ratio.
- They have low maintenance and corrosion resistance.

5. Design Validation

5.1 Optimal speed, glide angle, range, descent rate for the designed glider

- Glider at height 1000 meters and it have to travel range 30,000 meters range.
- Glider will be released from height more than 1000 meter so that it will take some altitude to reach equilibrium state.
- In this calculation we have considered the steady state of glider and estimated the values of C_l and C_d .
- We need glide ratio to be equal or more than 30:1.
- We need

$$\frac{L}{D} = \frac{C_l}{C_d} \geq \frac{30}{1}$$

C_l/C_d vs Alpha curve for Glider

Taking value of C_l and C_d for which C_l/C_d is greater than 30.

Consider

$$C_l = 0.793$$

$$C_d = 0.0146$$

$$\text{Angle of attack} = 6 \text{ degree}$$

Now estimating value of speed by putting the values of Weight, S_{ref} , Density of air, glide ratio.

$$\text{Optimised Speed} = 28.76 \text{ m/s}$$

$$\text{Lift} = 9545.43 \text{ N}$$

$$\text{Drag} = 175.74 \text{ N}$$

$$\text{Glide Ratio} = \frac{1}{\tan(\theta)} = \frac{C_l}{C_d} = \frac{\text{Range}}{\text{Altitude}}$$

$$\text{Altitude} = 1000$$

$$\text{Glide Angle} = \theta$$

$$\text{Glide Angle} = 1.054 \text{ degree}$$

$$\text{Range} = 54.31 \text{ km}$$

$$\text{Decent Rate} 0.1673 \text{ m/s}$$

5.2 Comment on glider performance w.r.t original requirement and possible scope for improvements.

- Glider's wing ratio must have aspect ratio in range of 30:1 to 60:1, and provide large range, aspect ratio can be increased.
- Glider can be given wing tip and more dihedral to improve its stability, wing tips will reduce induced drag will increase range and roll stability will be increased.
- Fuselage cross-section must be minimised to reduce form drag and to improve its performance.
- We can keep forward swept wing the advantage in this is that during stall it will happen from root chord to tip chord which will prevent the stall of part of wing which have control surfaces.
